

SOYBEAN VARIETIES' DISEASE RATINGS–2014

Dr. Tom Allen, Extension Plant Pathologist at DREC-Stoneville, has posted Frogeye Leaf Spot (FLS), Cercospora Blight (CB), and Septoria Brown Spot (SBS) ratings for MG IV and MG V soybean varieties that were in the 2014 Mississippi Soybean Variety Trials.

Varieties were rated for FLS, CB, and SBS at locations indicated in the below tables. Ratings were based on a scale of 0 to 9, where 0 = no disease present and 9 = severe disease symptoms.

Ratings are based on each variety's reaction to natural infestations of each disease at each location; i.e., plants were not inoculated with disease pathogens. Thus, the ratings do not presume to indicate a variety's response to a known yield-reducing level of the pathogen. Rather, the ratings are to be used as an indicator of each variety's reaction to the level of the pathogen present at each location in 2014.

According to Dr. Allen, consider the reaction of a particular variety across several locations when assessing that variety's susceptibility to the rated diseases.

Statistics

LSD (least significant difference). These values are used as a statistical tool to determine significant differences among variety ratings. The average ratings of any two varieties being compared must differ by more than the LSD value to be considered different in a particular test.

Put another way, the LSD is the smallest difference between ratings of two varieties that can be attributed to an actual difference in the varieties' disease susceptibility in a particular trial. Thus, a difference in the ratings of two varieties that exceeds the LSD is attributable to a difference in the disease susceptibility of the two varieties. Even though the average ratings of two varieties may be numerically different, the two disease ratings are not considered significantly different if that difference does not exceed the test LSD.

Probability level (*p* value). A disease rating difference between two varieties that exceeds the LSD value will be expected to do so 9 times out of 10 at the 10% (.10) level of probability, 19 times out of 20 at the 5% (.05) level, 99 times out of 100 at the 1% (.01) level, etc. The smaller the probability level, the more stringent the statistical test.

CV (coefficient of variation) and/or R² (coefficient of determination). These values are a measure of the relative precision of a given trial and can be used to compare the relative precision of different trials. The CV is generally considered to be an estimate of the amount of unexplained variation in a given trial or test, while the R² is a measure of the amount of variation that is explained or accounted for in a given test. A CV below 10% (10% unexplained variation in a trial) is desired, while an R² above 0.90 (90% of the variation in a trial has been accounted for) is desired.

Composed by Larry G. Heatherly, Dec. 2014, larryheatherly@bellsouth.net
